# Monthly Stock Market Report

**This document is for internal use only. The document or any of its contents should not be distributed outside of the Federal Reserve System without permission.**

Market Analysis for Period Ending Friday, November 29, 2002

This document presents technical and fundamental analysis commonly used by investment professionals to interpret direction and valuation of equity markets, as well as tools commonly used by economists to determine the health of financial markets and their impact on the domestic United States economy. The purpose is to provide a synopsis of equity markets from as many disciplines as possible, but is in no way an endorsement of any one mode of study or source of advice on which one should base investment decisions.

Definitions of terms and explanations of indicator interpretation follow the charts in the Endnotes section.

---

## Technical Trends

Figure 1 presents price trends and daily volumes for the New York Stock Exchange and Nasdaq Composite Indices.

The New York Stock Exchange Composite Index (NYSE Index) closed Friday, November 29 at 495.27. After establishing a new five-year low on October 9, the index has risen 17.6 percent. Still, this level marked an 18.8 percent decline since the recent high of 609.53 on March 19. The index is down 16.0 percent in 2002, and has lost 13.2 percent just since the beginning of June.

The National Association of Securities Dealers Composite Index (Nasdaq Index) closed at 1478.78, down 24.2 percent for the current year. On October 9, the index fell to its lowest point since August 1996, but has increased 32.7 percent in just seven weeks (figure 1).

Figures 2, 3, and 4 present some technical indicators commonly cited by stock market analysts.

As of November 29, the relative strength index for the NYSE Composite had a value of 59.9 percent, a figure normally interpreted as neutral (figure 2, upper panel). The number of stocks falling to new 52-week lows has declined sharply since the beginning of October, while the number of stocks making new highs has remained small (figure 3 upper panel). The middle panel shows that momentum (overbought/oversold oscillator) is in overbought territory and increasing, which could

be seen as bearish. The Market Breadth indicator (figure 3, bottom panel) has seen a slight increase.

For the Nasdaq Index, the relative strength remains neutral, though close to overbought territory (figure 2). The upper panel in Figure 4 shows that the number of stocks reaching new lows has fallen sharply in the last two months, while the number of stocks reaching new highs has started to rise. Advancing stocks have outnumbered declining ones recently (lowest panel, figure 4). The momentum indicator is in overbought territory and rising, a potentially bearish indicator (figure 4, middle panel).

### **Volatility**

Indicators of market volatility are shown in figure 5.

The Chicago Board of Options Exchange (CBOE) provides daily measures of volatility for the S&P 100 (VIX) and for the Nasdaq 100 (VXN). Volatility remains historically high, though both indices are more than halfway back from their peaks from early October.

Put/Call ratios appear in figure 6.

Monthly data are shown from January 1997 through October 2002. Both the CBOE individual equity put/call ratio and the S&P 100 put/call ratio declined in October and are at or near bullish territory. This indicator does not take into account the strong November performance of the equity markets.

### **Sector Performance**

Figure 7 compares the performance of the various economic sectors within the S&P 500 as well as other international and style indices.

None of the ten economic sectors in the S&P 500 have a positive year-to-date return as of November 29. Utilities has overtaken telecommunications for the largest loss; the sector is down 35.4 percent for the year. Information technology had the largest return over the past five years, but is down 27.1 percent for 2002. The consumer staples and materials sectors, which had the smallest returns from 1997 through 2001, are the only sectors to avoid a double-digit loss so far this year (figure 7, top panel).

The Wilshire 5000, composed of all U.S. equity issues, has lost 17.4 percent year-to-date. Still, the losses for the German DAX (35.3 percent loss in 2002) and British FTSE 100 (20.1 percent loss) have been greater. The Japanese Nikkei 225 has experienced a 12.6 percent loss in 2002 (figure 7, middle panel).

For much of 2002, the Russell 2000 Small-Cap index outperformed the Russell 1000 Large-Cap index. However, the Russell 1000 is back to break-even for the year, while the Russell 2000 is down 16.8 percent (figure 7, bottom panel). Growth stocks returned 15.2 percent in the years 1997 through 2001, but have declined 23.2 percent this year. Value stocks have declined 16.8 percent, as measured by the Russell 1000 Value Index.

## Valuation

Figure 8 displays historical and current price-earnings ratios for the S&P 500 economic sector groups described above. Figure 9 graphs the current and previous earnings forecasts for several calendar years in the top panel, and lists the current and previous growth of earnings forecasts for each S&P 500 sector in the two tables. Figure 10 shows three measures of historical and future valuation: historical PE ratios in the top panel, forward and trailing PE ratios using analysts' estimates of operating earnings in the middle panel, and strategists' two-year forecasts of earnings growth in the lower panel.

Declining prices have finally deflated some of the extraordinary price-earnings ratios seen in many industries. Among the economic sectors, price-earnings ratios have increased for about half of the ten sectors since the fourth quarter of 2000. The energy sector has risen the most, from 21.4 to 39.5. The health care sector's ratio has fallen from 42.2 in the fourth quarter of 1998 to 26.5 as of November 29, due to both a decline in stock prices and an increase in earnings (figure 8, top panel).

The analysts surveyed by Thomson Financial/First Call report a 14.9 percent increase in earnings for the S&P 500 in the fourth quarter of 2002, and a 1.9 percent increase for the calendar year. Analysts have cut earnings expectations for the fourth quarter for eight of the eleven sectors, often sharply, since the quarter began. In the fourth quarter, the materials and transportation sectors are expected to experience the biggest increase in earnings, but those sectors had especially poor earnings in the fourth quarter of 2001. Earnings for the utilities sector are expected to continue to suffer after a poor third quarter (figure 9).

The macro projections from strategists for the growth of earnings for the Standard and Poor's 500 index over the next two years have been revised downward to 2.9 percent in the third quarter of 2002. The **S&P 500 trailing price-earnings ratio** decreased from 37.0 in the second quarter of 2002 to 27.5 in the third quarter. During the third quarter, the price-earnings ratio for the Russell 2000 decreased to 29.9 from 39.5. The fourth quarter forecast for the **S&P 500 forward price-to-operating-earnings**

**ratio**, using bottom-up forecasts from analysts, increased to 17.5 from 15.3 in the third quarter (figure 10).

### **Breadth of the S&P 500**

Prices rose for 41.3 percent of stocks in the S&P 500 in the second quarter of 2002, down from 64.9 percent in the first quarter (figure 11, middle panel). Although the median price to operating earnings ratio dropped for all deciles of the S&P 500, only three deciles have median ratios below the historical average price-to-earnings ratio of 14.4 (figure 11, bottom).

### **Comparative Returns**

The dividend-price ratio, an indication of the yield investors receive through dividends by holding stocks, increased to 1.5 percent in the second quarter from 1.4 percent in the first quarter. The earnings-price ratio increased to 2.5 percent in the second quarter from 2.2 percent in the first quarter. Both of these ratios are still substantially below the 5.0 percent real rate of interest on corporate bonds and their respective historical averages, 2.97 percent and 6.11 percent (figure 12). Typically, the earnings-price ratio falls below the real return on bonds when analysts expect earnings to rise rapidly.

Nonfinancial corporate businesses have tried to maintain dividends in the face of sagging profits, resulting in an unusually high dividend to operating profit payout rate of 62.9 percent, just below the highest ever recorded (figure 13, lower panel).

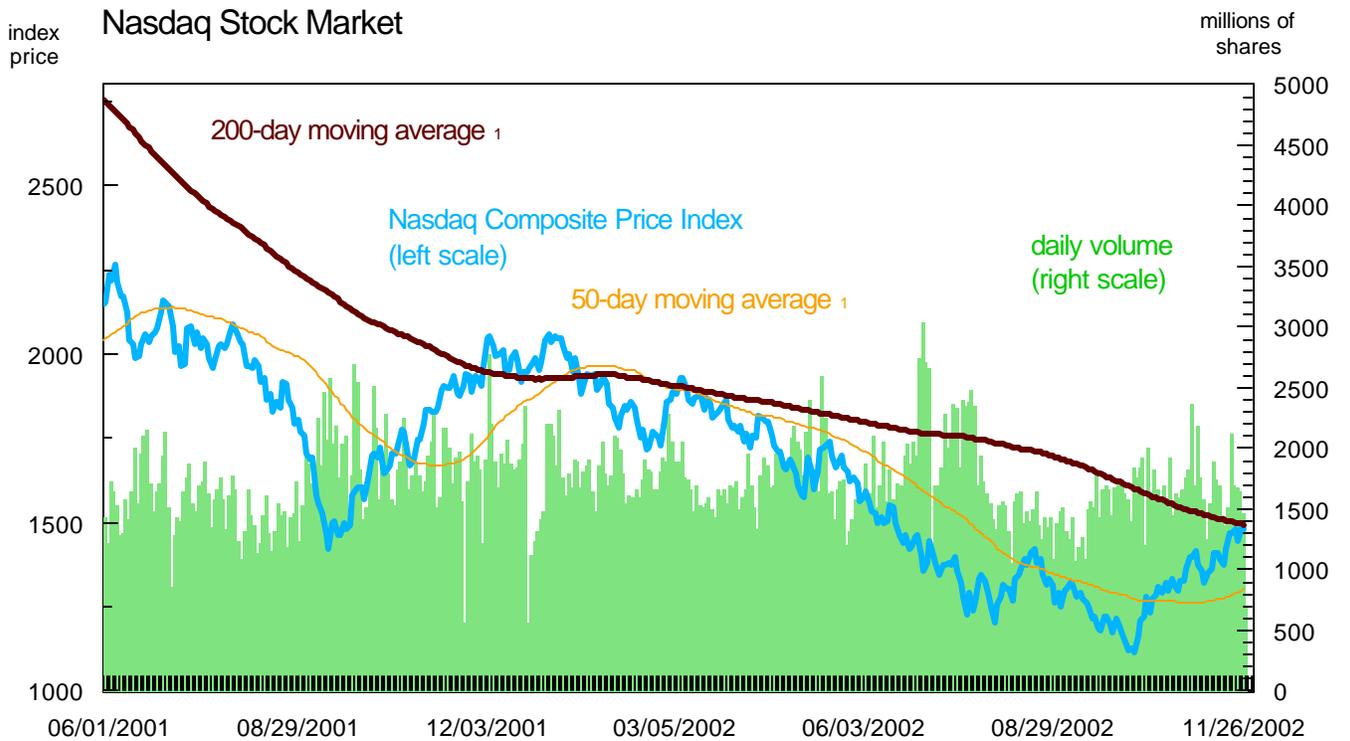

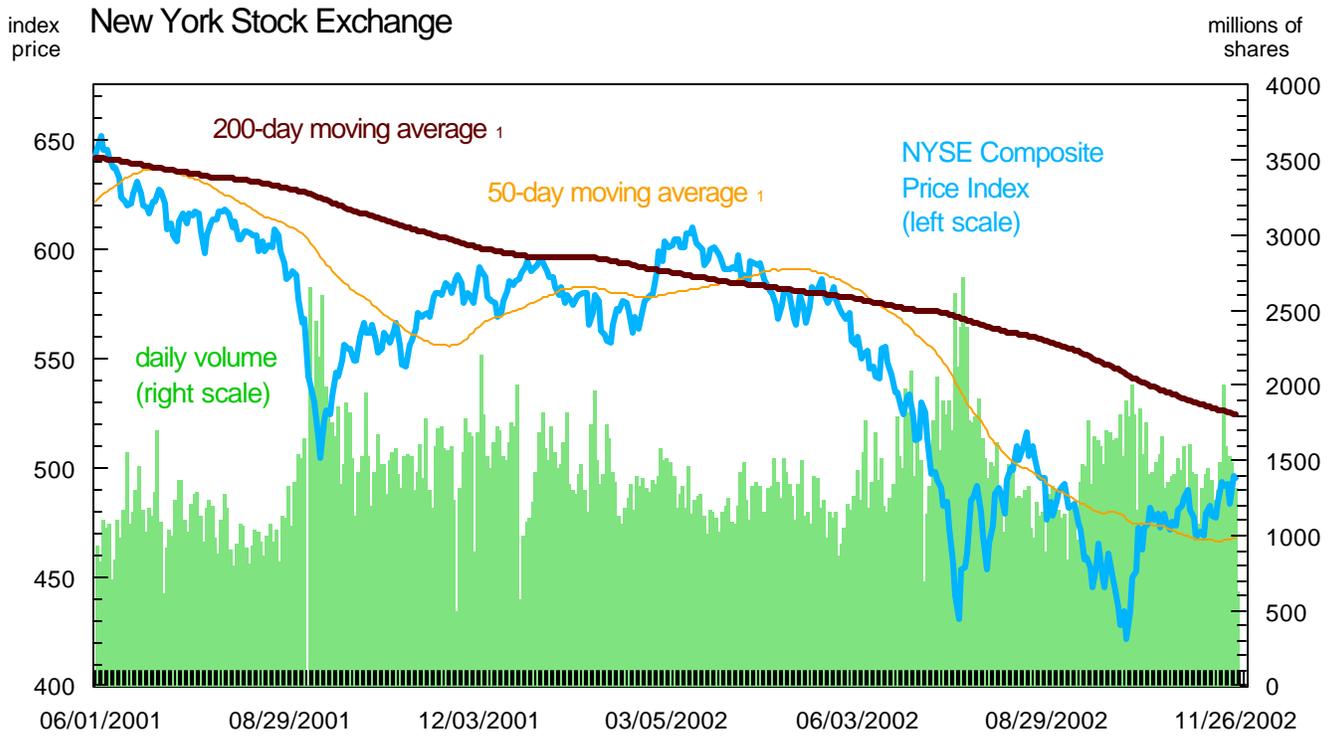

Moody's upgraded more investment grade securities and downgraded more speculative grade securities in October than in September (figure 15, top and middle panels). The default rate on junk bonds has declined slightly, from 22.8 in September to 21.5 in October (figure 15, lower panel).

## Endnotes

1. 50-Day, 200-Day Moving Average: Moving averages represent the average price investors paid for securities over a historical period, and present a smoothed picture of the price trends, eliminating the volatile daily movement. Because these lines offer a historical consensus entry point, chartists look to moving average trend lines of index prices to define levels of support or resistance in the market. When a chart trend is predominantly sideways (Figure 1, top chart), moving averages and the underlying series frequently cross, but during a time of prolonged increase or decrease (bottom chart) the daily prices of a security typically are above or below the trailing average. Moving above or below the 50-day moving average is sometimes associated with rallies or corrections. Similarly, prolonged movements, such as bull and bear markets can be represented by securities remaining above or below their 200-day moving average for prolonged periods of time.
2. 9-Day, 18-Day Moving Averages: The 9-day and 18-day moving averages are often used together to provide buy and sell signals. Buy signals are indicated by the 9-day average crossing above the 18-day when both are in an uptrend. The reverse, the 9-day crossing below the 18-day while both moving averages are declining is a sign to sell. However, this simple can often be misleading because of its dependence on trending markets and inability to capture quick market turns.
3. Relative Strength Index: This (RSI) momentum oscillator measures the velocity of directional price movements. When prices move rapidly upward they may indicate an overbought condition, generally assumed to occur above 70 percent. Oversold conditions arise when prices drop quickly producing RSI readings below 30 percent.
4. New Highs, New Lows: A straightforward breadth indicator, this is the 10-day moving average of the number of stocks on a given index or exchange making new 52-week highs or lows each day. This indicator also demonstrates divergence. If an index makes a new low, but the number of stocks in the index making new lows declines, there is positive divergence, and in this case a lack of downside conviction. Conversely, In rising markets if an index makes a new high but the number of individual stocks in that index making new highs does not increase this suggests a false rally.
5. Overbought / Oversold Oscillator: This momentum indicator is calculated by taking the 10-day moving average of the difference between the number of advancing and declining issues for a given index. The goal of the indicator is to show whether an index is gaining or losing momentum, so the size of the moves are more important than the level of the current reading. This is first affected by how the oscillator changes each day, by dropping a value ten days ago, and adding one today. If the advance decline line read minus 300 ten days ago, and minus 100 today, even though the market is down again, the oscillator will rise by 200 because of the net difference of the exchanged days' values. This suggests a

trough, however, if today's reading was minus 500 it would demonstrate a gain in downside momentum.

The magnitude in moves is useful when compared with divergence to the index price. If the Dow peaks at the same time the oscillator peaks in overbought territory, it suggests a top. If the index then makes a new high but the oscillator fails to make a higher high, divergence is negative and momentum is declining. If the index at this point declines and the oscillator moves into oversold territory it may again be time to buy. If the index rises but does not make new highs, but the oscillator continues to rise above a previous overbought level, upside momentum exists to continue the rally.

6. **Cumulative Advance / Decline Line:** Referred to as market breadth, the indicator is the cumulative total of advancing minus declining issues each day. When the line makes new highs a rally is considered widespread, but when lagging a rally is seen as narrow.
7. **Volatility:** With regard to stock prices and stock index levels, volatility is a measure of changes in price expressed in percentage terms without regard to direction. This means that a rise from 200 to 202 in one index is equal in volatility terms to a rise from 100 to 101 in another index, because both changes are 1 percent. Also, a 1 percent price rise is equal in volatility terms to a 1 percent price decline. While volatility simply means movement, there are four ways to describe this movement:
  1. *Historic volatility* is a measure of actual price changes during a specific time period in the past. Mathematically, historic volatility is the annualized standard deviation of daily returns during a specific period. CBOE provides 30 day historical volatility data for obtainable stocks in the Trader's Tools section of this Web site.
  2. *Future volatility* means the annualized standard deviation of daily returns during some future period, typically between now and an option expiration. And it is future volatility that option pricing formulas need as an input in order to calculate the theoretical value of an option. Unfortunately, future volatility is only known when it has become historic volatility. Consequently, the volatility numbers used in option pricing formulas are only estimates of future volatility. This might be a shock to those who place their faith in theoretical values, because it raises a question about those values. Theoretical values are only estimates, and as with any estimate, they must be interpreted carefully.
  3. *Expected volatility* is a trader's forecast of volatility used in an option pricing formula to estimate the theoretical value of an option. Many option traders study market conditions and historical price action to forecast volatility. Since forecasts vary, there is no specific number that everyone can agree on for expected volatility.
  4. *Implied volatility* is the volatility percentage that explains the current market price of an option; it is the common denominator of option prices. Just as p/e ratios allow comparisons of stock prices over a range of variables such as total

earnings and number of shares outstanding, implied volatility enables comparison of options on different underlying instruments and comparison of the same option at different times. Theoretical value of an option is a statistical concept, and traders should focus on relative value, not absolute value. The terms "overvalued" and "undervalued" describe a relationship between implied volatility and expected volatility. Two traders could differ in their opinion of the relative value of the same option if they have different market forecasts and trading styles.

8. CBOE Volatility Index (VIX): The VIX, introduced by CBOE in 1993, measures the Volatility of the U.S. equity market. It provides investors with up-to-the-minute market estimates of expected volatility by using real-time OEX index option bid/ask quotes. This index is calculated by taking a weighted average of the implied volatilities of eight OEX calls and puts. The chosen options have an average time to maturity of 30 days. Consequently, the VIX is intended to indicate the implied volatility of 30-day index options. It is used by some traders as a general indication of index option implied volatility. (Source: CBOE)
9. CBOE NASDAQ Volatility Index (VXN): Like the VIX, the VXN measures implied volatility, but in this case for NASDAQ 100 (NDX) index options, thereby representing an intraday implied volatility of a hypothetical at-the-money NDX option with thirty calendar days to expiration. Both the VXN and the VIX are used as sentiment indicators for the NASDAQ 100 and for the broader market, respectively. Higher readings and spikes generally occur during times of investor panic and at times coincide with market bottoms. Low readings suggest complacency and often occur around tops in index prices.
10. Put / Call Ratio: These ratios are used as contrary sentiment indicators. Higher ratio values, indicating more put trading, is considered more bullish. The CBOE index ratio tracks trade volume of all exchange traded index options, reflecting sentiment of professional and institutional strategies. The CBOE equity ratio is composed of trade volume for individual equity options and a better indicator of retail investor sentiment. Equity ratio readings 60/100 and 30/100 denote levels of bullishness and bearishness. Similarly, bullish and bearish boundaries for the S&P 100 are 125/100 and 75/100.
11. 2-Year Growth of Earnings: Growth of earnings over subsequent 8 quarters. Current observations use forecast of earnings from macro projections.
12. Earnings and Dividend Price Ratios: These ratios represent an investor's yield from earnings and dividend payments. Historically, the EP ratio often has exceeded the real return on bonds, reflecting the greater risk to shareholders for choosing equity investments. Recently, the EP ratio has fallen below the return on bonds as investors demand uncharacteristically large capital gains to compensate for the low earnings yield. Historically, the EP ratio has fallen below the real bond rate only when earnings are expected to rise dramatically.

13. Real Bond Rate: Moody's composite yield of A-rated corporate bonds less the expected rate of inflation over the next 10 years as measured by the consumer price index from the Survey of Professional Forecasters, published by the Federal Reserve Bank of Philadelphia.
14. Moody's Ratings: Denotes the change in dollar amount of investment grade (above BA1) or speculative grade (BA1 or below) securities outstanding for a particular company if that company is up/downgraded during a given month. For example, if company XYZ was upgraded, and they had bonds rated AA2 for \$10, AA1 for \$2, and A3 for \$15, this company's contribution to the chart value is \$27.
15. Investor Expectations: Internally generated composite of the Conference Board's 12-month forward investor expectations for no change, increase, and decrease in the stock market. Composite values of 50 indicate neutral expectations. Values below 50 demonstrate bearish sentiment, though the chart demonstrates that the outlook of investors is typically bullish.
16. Tobin's q: The ratio of the market value of equity plus net interest bearing debt to current value of land, inventories, equipment, and structures.
